Advanced Network Analysis

A Local Structure Graph Model

Olga Chyzh [www.olgachyzh.com]

Readings

- Emily Casleton, Daniel Nordman, and Mark S. Kaiser. A local structure model for network analysis. *Statistics and Its Interface*, 2(10), 2017.
- Olga V. Chyzh and Mark S. Kaiser. Network analysis using a local structure graph model. *Political Analysis*, 27(4):397{414, 2019.

Motivation

- Do edges among red nodes affect the formation of edges among turquoise nodes?
- If nodes 6 and 7 formed and edge, would that make it more likely that nodes 3 and 4 form an edge?

The Estimator

- ullet Suppose i is an potential edge in a network of potential edges (realized and unrealized);
- Then $s_i=(u_i,v_i)$ is i's location in Cartesian space.
- Denote the binary random variable, $y(s_i) = y_i$, so that:

$$y(s_i) = egin{cases} 1 & ext{if edge } s_i ext{ is present} \ 0 & ext{if edge } s_i ext{ is absent.} \end{cases}$$

- Define i's neighbors as $N_i = \{s_j : s_j \text{ is a neighbor of } s_i\}$.
- Make a Markov assumption of conditional spatial independence:

$$f(y(s_i)|\mathbf{y}(s_j):s_j
eq s_i) = f(y(s_i)|\mathbf{y}(N_i))$$

• If connectivities between edges are continuous, then the Markov assumption is redundant.

The DV

Set Up the Connectivity Matrix, W

- Start with an adjacency matrix among all potential edge-pairs.
- Code two edges as connected if they connect opposite-colored pairs of same-colored nodes.

The Binary Conditional Distribution

$$P(Y_i = y_i | \boldsymbol{y}(N_i)) = \exp[A_i(\boldsymbol{y}(N_i))y_i - B_i(\boldsymbol{y}(N_i))], \tag{1}$$

where A_i is a natural parameter function and $B_i = \log[1 + \exp(A_i(y(N_i)))]$, and $\mathbf{y}(N_i)$ is a vector of values of the binary random variables (edges) of i's neighbors.

The Natural Parameter Function

$$A_{i}\left(oldsymbol{y}\left(N_{i}
ight)
ight) = \log\!\left(rac{\kappa_{i}}{1-\kappa_{i}}
ight) + \eta \sum_{j\in N_{i}}w_{ij}\left(y_{j}-\kappa_{j}
ight),$$
 (2)

where $\log\left(\frac{\kappa_i}{1-\kappa_i}\right) = \boldsymbol{X}_i^T\boldsymbol{\beta}$, \boldsymbol{X}_i is a column vector of k exogenous covariates, $\boldsymbol{\beta}$ is a k by 1 vector of estimation parameters, w_{ij} is the ij^{th} element of a matrix of connectivities among edges \textbf{W}, and η is its parameter.

- When $y_j > \kappa_j$, then the dependence term makes a positive contribution to $A_i(\mathbf{y}(N_i))$ ---complementary processes;
- When $y_j < \kappa_j$, then the dependence term makes a negative contribution to $A_i(\mathbf{y}(N_i))$ ---substitution-type processes;
- Key condition: $w_{ij} = w_{ji}$.
- Model does not require (prohibits) row-standardization of w.

Estimation

$$\log PL = \sum_{i} \{y_i \log(p_i) + (1 - y_i) \log(1 - p_i))\}, \tag{3}$$

where:

$$p_i = rac{\exp[A_i(y(N_i))]}{1 + \exp[A_i(y(N_i))]}$$
 (4)

Let's Program This

```
#Likelihood
loglik<-function(par,W,Y){</pre>
b0<-par[1]
eta<-par[2]
X<-rep(1,length(Y))</pre>
xbeta<-as.matrix(X)%*%b0</pre>
kappa<-exp(xbeta)/(1+exp(xbeta)) #logit of Xb</pre>
A_i=log(kappa/(1-kappa))+eta*W%*%(Y-kappa) #Eqn 2
p_i \leftarrow exp(A_i)/(1+exp(A_i)) #Eqn 1, also Eqn 4
PL \leftarrow Y * log(p_i) + (1-Y) * log(1-p_i) #Eqn 3
ell <- -sum(PL)
#cat("ell",ell, fill=TRUE)
return(ell)
```

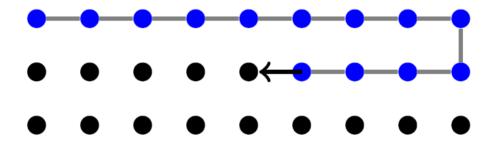

Let's Estimate

```
m1<-optim(par=c(0,0),loglik,W=Wmat,Y=Y)</pre>

```

Estimating Standard Errors

Need to simulate *Y* based on our parameter estimates:

- Start from a vector of initial $y_0 = \{y_{01}, y_{02}, \dots, y_{0n}\}$ drawn from a binomial distribution;
- Moving row-wise, for i = 1, ..., n, individually simulate/update each observation as a function of previously simulated observations:

- n individual updates provide 1 full Gibbs iteration
- Use the result of step 2 as the new initial values and repeat step 2 to obtain M simulated networks *y* (can burn-in, thin, etc.).

Simulate Networks Based on m1

- 1. Function spatbin genone simulates/updates a value for y for a single observation--step 2
- 2. Function spatbin.onegibbs applies spatbin.genone to update every observation of y--step 3
- 3. Function spatbin.genfield applies spatbin.onegibbs to generate ${\cal M}$ networks --step 4

```
spatbin.genone<-function(coeffs,w,curys){
b0<-coeffs[1]
eta<-coeffs[2]
X<-rep(1,length(Y))
xbeta<-as.matrix(X)%*%b0
kappa<-exp(xbeta)/(1+exp(xbeta))
A_i=log(kappa/(1-kappa))+eta*w%*%(curys-kappa)
p_i<- exp(A_i)/(1+exp(A_i))
y<- rbinom(n=length(curys), size=1, prob=p_i)
return(y)
}</pre>
```

```
spatbin.onegibbs<-function(coeffs,w,curys){
cnt<-0
n<-length(curys)
newys<-NULL
repeat{
    cnt<-cnt+1
    ny<-spatbin.genone(coeffs=coeffs,w=w,curys=curys)
    curys[cnt]<-ny[cnt]
    if(cnt==n) break
    }
newys<-curys
return(newys)
}</pre>
```

```
spatbin.genfield<-function(coeffs,w,y0s,M) {
  curys<-y0s
  cnt<-0
  res<-as.data.frame(y0s)
  repeat{
      cnt<-cnt+1
      newys<-spatbin.onegibbs(coeffs=coeffs,w=w,curys=curys)
      curys<-newys
      res<-cbind(res,curys)
      if(cnt==M) break
      }
  return(res)
}</pre>
```

```
n<-length(Y)
y0s=rbinom(n=n, size=1, prob=.5)
sims<-spatbin.genfield(coeffs=m1$par,w=W,y0s=y0s,M=1000)
#Take every 10th simulated network, i.e. burnin=10, thinning=10
sims<-sims[,seq(from=10, to=ncol(sims),by=10)]</pre>
```

Obtaining Standard Errors

- 1. Estimate the model on simulated networks (after burnin and thinning);
- 2. The standard errors are the standard deviations of the estimated coefficients.
